Private branch radio communication system using optical fibers.

A private branch radio communication system includes a portable radio transmitter (1) and a portable radio receiver (4). The system further includes first and second repeaters (2, 3) respectively located in first and second areas (P1, P2) within a given premises and coupled to each other through an optical fiber cable (5). A radio signal output from the portable radio transmitter (1) is converted into an optical signal by the first repeater (2), and is then supplied to the second repeater (3) through the optical fiber cable (5), and converted into a radio signal which is received by the portable radio receiver (4).

Private branch radio communication system using optical fibers

The present invention relates to a private branch radio communication system and, more particularly, to a private branch radio communication system using optical fibers.

On sites such as power plants or substations, large numbers of personnel may be engaged in jobs related to each other, but often doing so in widely separated locations throughout the site. For this reason, a radio communication system is generally used to enable personnel to communicate with each other, with each worker carrying a portable radio transceiver while doing his job, and exchanging information with other personnel, as and when required.

This type of radio communication system utilizes a relatively weak radio wave, this being because if a strong radio wave were to be used, it might interfere with the operation of various electronic devices located on the same premises.

If radio communication is to be performed in a building, especially in a so-called intelligent building in which various systems, such as the air conditioning system, for example, are computer-controlled, a very weak radio wave, e.g., a radio wave having a field intensity of 500 $\mu\text{V/m}$ or less which is measured at, for example, a position 3 m away from a radio wave source, should preferably be used in order to prevent erroneous operation of various electronic devices in the building, as a result of radio interference. However, in buildings, the transmitting of radio waves tends to be hindered by walls, pillars, and the like. Therefore, when a weak radio wave is, for the aforesaid reasons, used for communication within a building, satisfactory communication from the ground floor to the uppermost floor cannot be achieved. For this reason, radio communication using a weak radio wave can be employed only for private branch communication within a confined area, e.g., within one floor of a building, but not throughout all floors of the building. As a result, the range through which personnel can move and remain in communication is undesirably limited.

Accordingly, it is an object of the present invention to provide a private branch radio communication system using a weak radio wave but capable of providing excellent radio communication over a wide area, such as throughout a given premises or site.

According to the present invention, there is provided a private branch radio communication system comprising a portable radio transmitter for modulating a signal and outputting the modulated signal as a radio signal in a first area within a given premises, a first repeater, located in the first area,

for receiving the radio signal transmitted from the radio transmitter and outputting an optical signal corresponding to the signal received; an optical transmission medium for transmitting the optical signal output from the first repeater to a second area within the premises, a second repeater, located in the second area, for receiving the optical signal output from the first repeater and transmitted by the optical transmission medium, and generating a radio signal corresponding to the signal received in the second area, and a portable radio receiver for receiving the radio signal output from the second repeater in the second area and demodulating the signal received.

In the above-described private branch radio communication system, the first and second repeaters are, as described above, located in the first and second areas, respectively, and are coupled to each other through an optical fiber cable. As a result, a radio signal generated from the portable radio transmitter is not transmitted directly from the first area to the second area by radio transmission, but is first converted into an optical signal by the first repeater in the first area, the optical signal is then transmitted through the optical fiber cable to the second repeater in the second area, and is converted by the second repeater back into a radio signal which is received by the portable radio receiver.

As described above, since communication between the first and second areas is accomplished not by direct radio transmission but by means of an optical fiber cable, therefore even if the first and second areas are, for example, different floors in a building, or even different buildings, communication between the first and second areas is free from interference caused by obstacles to transmission, such as walls and pillars in the building or, in the latter case, other buildings in-between. Therefore, even when using a weak radio wave generated by a portable transmitter, the present invention is able to provide excellent private branch radio communication over a wide-ranging area.

In addition, since an optical signal transmitted through an optical fiber cable is not an electrical signal, such a signal is therefore free from electrical influences caused by various other electrical signal lines and it, in turn, does not adversely influence such signal lines.

Thus, the private branch radio communication system of the present invention, using a weak radio wave and an optical signal, provides excellent private branch radio communication while at the same time having minimal adverse influence on various other electrical devices and telephone lines.

This invention can be more fully understood from the following detailed description when taken in conjunction with the accompanying drawings, in which:

Fig. 1 is a block diagram showing a private branch radio communication system according to a first embodiment of the present invention;

Fig. 2 is a block diagram showing a private branch radio communication system according to a second embodiment of the present invention;

Fig. 3 is a block diagram showing a private branch radio communication system according to a third embodiment of the present invention;

Fig. 8 is a circuit diagram showing an arrangement of a portable radio transceiver used in the private branch radio communication system in Fig. 3.

Fig. 1 shows a private branch radio communication system according to a first embodiment of the present invention. Referring to Fig. 1, a first area P1 represents a specific place in a specific building or site, e.g., a specific floor in a building, and a second area P2 represents a place separated from the first area P1 by a relatively large distance, e.g., another floor in the same building as that of the first area P1, or another place within the same site as that of the first area P1.

This private branch communication system is designed to transmit a radio signal generated by a portable radio transmitter 1 used in the first area P1 to a portable radio receiver 4 used in the second area P2. In this system, the portable radio transmitter 1 and a repeater 2 are arranged in the first area P1. The radio transmitter 1 is carried by, e.g., a worker and is freely moved in the first area P1. The repeater 2 is fixed in a specific place of the first area P1. Similarly, the portable radio receiver 4 and a repeater 3 are arranged in the second area P2. The radio receiver 4 can be freely moved in the second area P2, and the repeater 3 is fixed in a specific place of the second area P2. The

repeaters 2 and 3 are coupled to each other through an optical fiber cable 5.

The portable radio transmitter 1 comprises a modulator 7 including an oscillator 6, an amplifier 8, and a transmitting antenna 9. The radio transmitter 1 modulates a carry signal by a modulation signal to be transmitted, e.g., a speech signal by using the modulator 7, and amplifying the modulated signal by using the amplifier 8, thus radiating the amplified signal in air as a radio signal through the antenna 9. The repeater 2 comprises a receiving antenna 10, an amplifier 11, and an optical modulator 12. The repeater 2 receives a radio signal output from the radio transmitter 1 through the antenna 10, amplifies the received signal by using the amplifier 11, and converts the signal into an optical signal by using the optical modulator 12, thus supplying the signal to the optical fiber cable 5.

The repeater 3 comprises an optical detector 13, an amplifier 14, and a transmitting antenna 15. The repeater 3 converts the optical signal, which is transmitted from the repeater 2 through the optical fiber cable 5, into an electrical signal by using the optical detector 13, and amplifies the electrical signal by using the amplifier 14, thereby radiating the amplified signal in air as a radio signal through the antenna 15. The portable radio receiver 4 comprises a receiving antenna 16, an amplifier 17, and a demodulator 18. The radio receiver 4 receives a radio signal output from the repeater 2 through the antenna 16, and amplifies the received signal by using the amplifier 17, thereby demodulating the signal by using the demodulator 18. As a result, the modulation signal (speech signal in this case) is extracted from the received signal.

Since both the radio transmitter 1 and the repeater 2 are present in the first area P1, communication therebetween can be satisfactorily performed by using a weak radio wave (e.g., a radio wave having a field intensity of 500 $\mu\text{V/m}$ or less which is measured at a position separated from the radio transmitter 1 by 3 m). Similarly, since both the radio receiver 4 and the repeater 3 are present in the second area P2, communication therebetween can be satisfactorily performed by using a weak radio wave (e.g., a radio wave having a field intensity of 500 $\mu\text{V/m}$ or less which is measured at a position separated from the repeater 3 by 3 m).

Since signal transmission over a relatively large distance from the first area P1 to the second area P2 is performed not by radio transmission but by means of the optical fiber cable 5, a signal from the first area P1 is transmitted to the second area P2 without loss caused by radio wave obstacles such as walls and pillars in a building, or buildings in a site. Therefore, even if a radio wave output from the radio transmitter 1 is weak, a radio signal can

satisfactorily be transmitted to the radio receiver 4 in an excellent state.

In addition, since an optical signal transmitted through the optical fiber cable 5 is not an electrical signal, the signal is free from electrical influences from various other electrical signal lines and does not influence them.

A signal to be transmitted by this private branch radio communication system is not limited to a speech signal, but may include image signals or various data signals. In addition, it may include analog or digital signals.

Fig. 5 shows a detailed arrangement of the repeater 2. As shown in Fig. 5, a circuit including a constant-voltage source 121 and a laser diode 122 is used as the optical modulator of the repeater 2. In this circuit, a light-emitting diode may be used in place of the laser diode 122.

Fig. 6 shows a detailed arrangement of the repeater 3. As shown in Fig. 6, a circuit including a photodiode 131 is used as the optical detector 13 of the repeater 13.

Since the repeaters 2 and 3 respectively perform only electrical/optical conversion and optical/electrical conversion, they can be realized by simple circuit arrangements respectively shown in Fig. 5 and Fig. 6.

Fig. 2 shows a private branch communication system according to a second embodiment of the present invention. This system is designed to realize duplex simultaneous communication between first and second areas P1 and P2. Referring to Fig. 2, a portable radio transceiver 21 and two-way repeater 22 are arranged in the first area P1. The radio transceiver 21 is carried by, e.g., a worker and is moved within the first area P1. The repeater 22 is fixed in a specific place of the first area P1. Similarly, a portable radio transceiver 24 and a two-way repeater 23 are arranged in the second area P2. The transceiver 24 is moved within the second area P2, and the repeater 23 is fixed in a specific place of the second area P2. The repeaters 22 and 23 are coupled to each other through optical fiber cables 5A and 5B.

The portable radio transceiver 21 includes a transmitting section 21A, a receiving section 21B, and a transmitting/receiving antenna 21C. The transmitting and receiving sections 21A and 21B respectively correspond to the transmitter 1 and the receiver 4 shown in Fig. 1. The radio transceiver 21 modulates and amplifies a signal to be transmitted, e.g., a speech signal by using the transmitting section 21A, and radiates the resultant signal in air as a radio signal having a carrier frequency f_1 through the antenna 21C. In addition, the radio transceiver 21 receives a radio signal having a carrier frequency f_1' through the antenna 21C, and amplifies and demodulates the received

signal by using the receiving section 21B. As a result, the modulation signal (speech signal in this case) is extracted from the received signal.

The two-way repeater 22 comprises a transmitting/receiving antenna 22C, an electrical/optical signal converting section 22A, and an optical/electrical signal converting section 22B. The electrical/optical converting section 22A and the optical/electrical modulator 22B respectively correspond to the repeaters 2 and 3 shown in Fig. 1. The repeater 22 receives a radio signal output from the transceiver 21 through the antenna 22C, and converts the received signal into an optical signal by using the electrical/optical converting section 22A, thereby supplying the signal to the optical fiber cable 5A. In addition, the repeater 22 converts an optical signal supplied through the optical fiber cable 5B into an electrical signal by using the optical/electrical converting section 22B, and radiates the converted signal in air as a radio signal having the carrier frequency f_1' through the antenna 22C.

The two-way repeater 23 comprises a transmitting/receiving antenna 23C, an optical/electrical converting section 23A, and an electrical/optical signal converting section 23B. The electrical/optical signal converting section 23B and the optical/electrical modulator 23A respectively correspond to the repeaters 2 and 3 shown in Fig. 1. The repeater 23 converts an optical signal supplied through the optical fiber cable 5A into an electrical signal by using the optical/electrical signal converting section 23A, and radiates the converted signal in air as a radio signal having the carrier frequency f_1 through the antenna 23C. In addition, the repeater 23 receives a radio signal having the frequency f_1' output from the transceiver 24 through the antenna 23C, and converts the received signal into an optical signal by using the electrical/optical converting section 23B, thereby supplying the signal to the optical fiber cable 5B.

The portable radio transceiver 24 comprises a transmitting/receiving antenna 24C, a transmitting section 24A, and a receiving section 24B. The transmitting and receiving sections 24A and 24B respectively correspond to the transmitter 1 and the receiver 4 shown in Fig. 1. The radio transceiver 24 modulates and amplifies a signal to be transmitted, e.g., a speech signal by using the transmitting section 24A, and radiates the resultant signal in air as a radio signal having the carrier frequency f_1 through the antenna 24C. In addition, the transceiver 24 receives a radio signal having the carrier frequency f_1 through the antenna 24C, and amplifies and demodulates the received signal by using the receiving section 24B. As a result, the modulation signal (speech signal in this case) is

extracted from the received signal.

Since the private branch radio communication system of the second embodiment employs different carrier frequencies for transmission and reception, duplex communication can be realized. In addition, since the two-way repeaters 22 and 23 are respectively distributed in the first and second areas P1 and P2, communication between the portable transceivers 21 and 24 can be performed by using a weak radio wave as in the first embodiment.

In this embodiment, the two optical fiber cables 5A and 5B are used for signal transmission between the repeaters 22 and 23. However, by properly utilizing optical components, signal transmission between the repeaters can be realized by a single optical fiber cable. Also, with the arrangement of the second embodiment, one-way alternate communication can be realized.

Fig. 3 shows a private branch radio communication system according to a third embodiment of the present invention. This system is designed to realize duplex communication not only between the two areas P1 and P2 as described in the first and second embodiments but also between arbitrary areas of a plurality of areas. In this system, the premises are divided into five areas P11 to P15. A two-way repeater and one portable radio transceiver or more are arranged in each area. More specifically, a two-way repeater Ra and two portable radio transceivers Ka1 and Ka2 are arranged in the area P11, a two-way repeater Rb and two portable radio transceivers Kb1 and Kb2 are arranged in the area P12, a two-way repeater Rc and a portable radio transceiver Kc1 are arranged in the area P13, a two-way repeater Rd and two portable radio transceivers Kd1 and Kd2 are arranged in the area P14, and a two-way repeater Re and two portable radio transceivers Ke1 and Ke2 are arranged in the area P15. A each range of these areas P11 to P15 is setting so that a weak radio wave can sufficiently propagate in the each area.

The repeater Ra is coupled to transmitting and receiving optical fiber cables 30a and 30b. Similarly, the repeaters Rb, Rc, Rd, and Re are respectively coupled to transmitting and receiving optical fiber cables 30b and 31b, 30c and 31c, 30d and 31d, and 30e and 31e.

An optical multiplexer 32 includes input ports coupled to the optical fiber cables 30a to 30e, and output ports coupled to the optical fiber cables 31a to 31e. The multiplexer 32 multiplexes all the optical signal supplied through the cables 30a to 30e, and outputs a multiplexed signal to the optical fiber cables 31a to 31e, respectively.

An operation of the above-described system will be described below. Assume that ten frequencies f1 to f5 and f1' to f5' are respectively assigned

to the transceivers Ka1 to Ke1. In this system, if a specific portable radio transceiver transmits a radio signal having the frequency f1, another portable radio transceiver which receives the signal sends back a radio signal having the frequency f1' as a response signal. Therefore, in this system, five channels allowing simultaneous communication are ensured, i.e., a first channel using the frequencies f1 and f1', a second channel using the frequencies f2 and f2', a third channel using the frequencies f3 and f3', a fourth channel using the frequencies f4 and f4', and a fifth channel using the frequencies f5 and f5'.

Each of the radio transceivers Ka1 to Ke1 can radiate a radio signal having any one of the frequencies f1 to f5 and f1' to f5', and can receive a radio signal having any of the frequencies f1 to f5 and f1' to f5'. In addition, each of the units Ka1 to Ke1 has a function of detecting a frequency used by another unit. With this function, each of the units Ka1 to Ke1 can output a radio signal by using an unused frequency, i.e., a free channel, thus preventing radio interference.

Speech communication using the system shown in Fig. 3 will be described below in a state wherein all of the above-described first to fifth channels are used.

Radio signals generated by this system are ten signals denoted by V1 to V5 and V1' to V5' respectively corresponding to the carrier frequencies f1 to f5 and f1' and f5'. If these radio signals V1 to V5 and V1' to V5' are signals having amplitude-modified waves, the radio signals V1 to V5 and V1' to V5' can be represented as follows:

$$\begin{aligned} V1 &= A(1 + si(t)\sin(2\pi f1t)) \\ V2 &= A(1 + sj(t)\sin(2\pi f2t)) \\ V3 &= A(1 + sk(t)\sin(2\pi f3t)) \\ V4 &= A(1 + sp(t)\sin(2\pi f4t)) \\ V5 &= A(1 + sq(t)\sin(2\pi f5t)) \\ V1' &= A(1 + si'(t)\sin(2\pi f1't)) \\ V2' &= A(1 + sj'(t)\sin(2\pi f2't)) \\ V3' &= A(1 + sk'(t)\sin(2\pi f3't)) \\ V4' &= A(1 + sp'(t)\sin(2\pi f4't)) \\ V5' &= A(1 + sq'(t)\sin(2\pi f5't)) \end{aligned}$$

where A is a constant and si(t), sj(t), sk(t), sp(t), sq(t), si'(t), sj'(t), sk'(t), sp'(t), and sq'(t) are modulation signals such as speech signals. For example, with respect to the radio signal V1 for speech communication which is transmitted from a given transceiver, the radio signal V1' is sent back from another transceiver as a response signal. Similarly, with respect to the radio signals V2, V3, V4, and V5, the radio signals V2', V3', V4' and V5' are respectively sent back as response signals.

When the radio signals V1 to V5 are respectively generated in the areas P11 to P15, these signals are respectively converted into optical signals by the repeaters Ra to Re so as to be trans-

mitted to the optical fiber cables 30a to 30e. The signals V1 to V5 are multiplexed by the optical multiplexer 32, and the multiplexed signal $V1 + V2 + V3 + V4 + V5$ is supplied to the optical fiber cables 31a to 31e. As a result, the multiplexed signals $V1 + V2 + V3 + V4 + V5$ are received by the repeaters Ra to Re. Thereafter, the multiplexed signals $V1 + V2 + V3 + V4 + V5$ are generated as radio signals in the areas P11 to P15.

In this manner, a signal transmitted from each portable radio transceiver is commonly supplied to the respective areas P11 to P15. Since the transceivers Ka1 to Ke1 can receive radio signals of all the frequencies, a transceiver as a source, i.e., a source operator must specify a transceiver as a destination, i.e., a destination operator. If the source operator transmits a signal for specifying a destination operator, e.g., a specific call code like a telephone number prior to transmission of a radio signal for speech communication in the same manner as in a known normal paging system, this problem can be solved. More specifically, the source operator superposes a call signal for specifying a destination operator on the frequency of a free channel (one of the frequencies f1, f2, f3, f4, and f5) and transmits it. Since the call signal is distributed to all the areas P11 to P15, a destination operator in any area can receive the call signal.

When a specific portable radio transceiver calls another specific portable radio transceiver in this manner, the called transceiver sends back a response signal. In this case, if the call signal has the carrier frequency f1, the called radio transceiver sends back the response signal V1' having the carrier frequency f1'. Similarly, the response signal V2' having the carrier frequency f2' is sent back with respect to a call signal having carrier frequency f2.

Similar to the above-described transmission signals V1 to V5, the response signals V1' to V5' thus generated are supplied to the optical multiplexer 32 through the optical fiber cables 30a to 30e and are multiplexed by the multiplexer 32. The multiplexed signal $V1' + V2' + V3' + V4' + V5'$ is commonly supplied to all the areas P11 to P12.

As described above, in the system of the third embodiment, since transmission signals from the respective areas are multiplexed by the optical multiplexer 32, and the multiplexed signal is supplied to all the areas, duplex communication can be performed between arbitrary areas.

Fig. 4 shows a detailed arrangement of the optical multiplexer 32. The multiplexer 32 comprises optical/electrical signal converters 33a to 33e, an adder 34 including resistors R1a to R1e and R2, an amplifier 36, and electrical/optical signal converters 35a to 35e. In the optical multiplexer 32

having the above arrangement, the signals V1 to V5 input as optical signals are respectively converted into electrical signals by the converters 33a to 33e, and are added to each other by the adder 34. The added signal $V1 + V2 + V3 + V4 + V5$ is amplified by the amplifier 36. The amplified signal is then supplied to converters 35a to 35e, and hence the signals $V1 + V2 + V3 + V4 + V5$ are supplied to the optical fiber cables 31a to 31e as optical signals, respectively.

Fig. 7 shows a detailed arrangement of each of the repeaters Ra to Re used in the system of the third embodiment shown in Fig. 3. Since the repeaters Ra to Re have the same arrangement, Fig. 7 shows an arrangement corresponding to the repeater Ra. Referring to Fig. 7, a transmitting/receiving antenna 72, a receiving section including an amplifier 73 and an electrical/optical signal converter 74, and a transmitting section including an amplifier 78 and an optical/electrical signal converter 77 are coupled to a hybrid circuit 71. An optical fiber cable 30a is coupled to the electrical/optical signal converter 74. An optical fiber cable 31a is coupled to the optical/electrical signal converter 77. The amplifiers 73 and 78 are respectively designed to cover all the frequency bands used in this system. The hybrid circuit 71 is designed to cause a signal to flow in a direction indicated by a solid arrow and not to flow in a direction indicated by a broken arrow.

Fig. 8 shows a detailed arrangement of each of the portable radio transceivers Ka1 to Ke1 used in the system of the third embodiment shown in Fig. 3. Each transceiver includes a hybrid circuit 80, a transmitting/receiving antenna 81, a receiving section 82, and a transmitting section 83.

The receiving section 82 includes a tuner 87, a detector 84, a call code detector 86, and a channel selecting circuit 88. The tuner 87 is constituted by 10 resonators respectively corresponding to the carrier frequencies f1 to f5 and f1' to f5', as shown in Fig. 8. The tuner 87 selectively outputs a channel selection signal from one of terminals T1 to T5' in accordance with a received carrier frequency. For example, when a radio signal having the carrier frequency f1 is received, a channel selection signal is output from the terminal T1 and is supplied to the channel selecting circuit 88. Upon reception of the channel selection signal from the terminal T1, the circuit 88 turns on a lamp (not shown) for indicating that the frequency f1 is used, and at the same time, controls the tuner 87 not to receive signals other than the frequency f1 until the contents of a call code are checked by the call code detector 86. Similarly, when a channel selection signal is supplied from the terminal T2, the circuit 88 turns on a lamp (not shown) indicating that the

frequency f2 is used, and at the same time, controls the tuner 87 not to receive signals other than the frequency f2 until the contents of a call code are checked by the call code detector 86. Such a control operation for channel selection by the channel selecting circuit 88 can be realized by various methods, e.g., a method of selectively interrupting supply of a power source voltage VC to each portion of a resonator.

The detector 84 is used to extract a modulation signal such as a speech signal from a signal received by the tuner 87. The extracted modulation signal is output to a terminal 85, and at the same time, is supplied to the call code detector 86. The call code detector 86 has a pre-assigned self code and compares it with a call code supplied from another radio transceiver. If they coincide with each other, the detector 86 generates a signal for turning on a switch S2 of the transmitting section 83.

The transmitting section 83 includes an oscillator 90, a transmission frequency switching circuit 89, a modulator 91, and switches S1 and S2. The circuit 89 is used to manually select carrier frequencies for transmission. For example, when the lamp for indicating that the carrier frequency f1 is used is turned on by the channel selecting circuit 88, the frequency f1 will not be used (since the frequency f1' is also used, the frequency f1' will not be used) and an unused frequency is selected. The modulator 91 modulates a carrier wave having a frequency selected by the circuit 89 by using a modulation signal such as a speech signal. The modulated signal is then radiated in air from the transmitting/receiving antenna 81 when one of the switches S1 and S2 is ON. The switch S1 is manually operated and is set in an ON state when signal transmission is to be performed. The switch S2 is controlled by an output signal from the call code detector 86 and is automatically set in an ON state when a call code is transmitted from another radio transceiver to its own channel.

As has been described above, according to the private branch radio communication system of the present invention, by combining a transmission medium using radio waves with a transmission medium using optical fibers, excellent communication can be provided in a wide range covering the entire premises even when a weak radio wave is used.

Claims

1. A private branch radio communication system characterized by comprising:
a portable radio transmitter (1) for modulating a signal and outputting the modulated signal as a radio signal in a first area within a given premises;

a first repeater means (2), located in the first area, for receiving the radio signal transmitted from said radio transmitter (1) and outputting an optical signal corresponding to the signal received;

5 an optical transmission medium (5) for transmitting the optical signal output from said first repeater to a second area within said premises;

a second repeater means (3), located in the second area, for receiving the optical signal output from said first repeater means (2) and transmitted by said optical transmission medium, and generating a radio signal corresponding to the signal received in the second area;

10 and a portable radio receiver (4) for receiving the radio signal output from said second repeater (3) in the second area and demodulating the signal received.

2. A system according to claim 1, characterized in that said portable radio transmitter (1) outputs a radio signal having a field intensity allowing the signal to be received in any part of the first area.

3. A system according to claim 1, characterized in that said second repeater means (3) outputs a radio signal having a field intensity allowing the signal to be received in any part of the second area.

4. A system according to claim 1, characterized in that said first and second repeater means (2, 3) are located in the first and second areas, respectively.

5. A system according to claim 1, characterized in that said first repeater means (2) includes a receiving antenna (10) and an electrical/optical converting means (12) for converting a radio signal received by said receiving antenna (10) into an optical signal.

6. A system according to claim 1, characterized in that said second repeater means (3) includes an optical/electrical converting means (13) for converting an optical signal transmitted through said optical transmission medium (5) into an electrical signal, and a transmitting antenna (15) for outputting, as a radio signal, the electrical signal output from said optical/electrical converting means (13) in the second area.

7. A private branch radio communication system characterized by comprising:

a first portable radio transceiver (21) for modulating a signal and generating the modulated signal as a radio signal in a first area within a given premises, and for receiving the radio signal generated in the first area and demodulating the signal received;

50 a second portable radio transceiver (24), for modulating a signal and generating the modulated signal as a radio signal in a second area within said premises, and for receiving the radio signal generated in the second area and demodulating the

signal received;

an optical transmission medium (5A, 5B) for coupling the first and second areas to each other;
 a first two-way repeater means (22), arranged in the first area, for receiving the radio signal output from said radio transceiver (21) and supplying an optical signal corresponding to the signal received to said optical transmission medium (5A, 5B) and for receiving an optical signal transmitted through said optical transmission medium (5A, 5B) and generating a radio signal corresponding to the signal received in the first area; and
 a second two-way repeater means (23), arranged in the second area, for receiving the optical signal output from said first repeater means (22) and transmitted through said optical transmission medium (5A, 5B), and generating a radio signal corresponding to the signal received in the second area and for receiving the radio signal output from said radio transceiver (24) and supplying an optical signal corresponding to the signal received to said optical transmission medium (5A, 5B).

8. A system according to claim 7, characterized in that said first portable radio transceiver (21) outputs a radio signal having a field intensity allowing the signal to be received in any part of the first area.

9. A system according to claim 7, characterized in that said second portable radio transceiver (24) outputs a radio signal having a field intensity allowing the signal to be received in any part of the second area.

10. A system according to claim 7, characterized in that said first two-way repeater means (22) outputs a radio signal having a field intensity allowing the signal to be received in any part of the first area.

11. A system according to claim 7, characterized in that said second two-way repeater means (23) outputs a radio signal having a field intensity allowing the signal to be received in any part of the second area.

12. A system according to claim 7, characterized in that said first and second two-way repeaters (22, 23) are located in the first and second areas, respectively.

13. A system according to claim 7, characterized in that said first two-way repeater means (22) includes a transmitting/receiving antenna (22C), electrical/optical signal converting means (22A) for converting a radio signal received by said transmitting/receiving antenna (22C) into an optical signal, and optical/electrical signal converting means (22B) for converting, into an electrical signal, an optical signal transmitted through said optical transmission medium (5A, 5B) and supplying the electrical signal to said transmitting/receiving antenna (22C).

14. A system according to claim 7, characterized in that said second two-way repeater means (23) includes a transmitting/receiving antenna (23C), electrical/optical signal converting means (23A) for converting a radio signal received by said transmitting/receiving antenna (23C) into an optical signal, and optical/electrical signal converting means (23B) for converting, into an electrical signal, an optical signal transmitted through said optical transmission medium (5A, 5B) and supplying the electrical signal to said transmitting/receiving antenna (23C).

15. A private branch radio communicating system characterized by comprising:

a plurality of portable radio transceivers (Ka1 - Ke1);

a plurality of two-way repeater means (Ra - Re), distributed throughout a plurality of areas (P11 - P15) within a given premises, for receiving radio signals generated in the respective areas where the repeater means are distributed and supplying optical signals corresponding to the signals received to a first optical transmission medium (30a - 30e), and for receiving optical signals input through a second optical transmission medium (31a - 31e) and generating radio signals corresponding to the signals received in the respective areas; and
 optical signal multiplexing means (32) for multiplexing the optical signals output from said plurality of two-way repeater means (Ra - Re) and supplied through said first optical transmission medium (30a - 30e), and supplying the multiplexed optical signal to said plurality of two-way repeater means (Ra - Re) through said second optical transmission medium (31a - 31e).

16. A system according to claim 15, characterized in that said plurality of portable radio transceivers (Ka1 - Ke1) are distributed throughout said plurality of areas (P11 - P15).
